Financial Claim Verification and SEC Fact-Checking System

End-to-End Automated Pipeline

TECHNICAL OVERVIEW | ENGINEERING ARCHITECTURE

Kritika Singh

Converting Unstructured Speech into Verifiable Financial Truth

OBJECTIVE

1. Ingest earnings call transcripts
2. Extract quantitative financial claims
3. Verify against official SEC regulatory filings

CORE CHALLENGE

- Moving beyond simple extraction to reliable, explainable verification
- Bridging the gap between executive rhetoric and regulatory ground truth

SPEECH TO TRUTH PIPELINE

System Architecture Overview

Key architectural decision:

- Transcript processing and SEC processing are independent
- They only interact at the verification layer
- This separation ensures modularity, testability, and scalability

Track A: Transforming Text into Structured Claims

PURPOSE
Convert raw, verbose, unstructured earnings call text into structured, machine-verifiable financial claims

Raw text

"Co. reported 1Q17 revenues of $78.4b, net income of $17.9b and diluted EPS of $3.36. Expects 2Q17 revenues to be $51.5-53.5b."

```
{
  "sec_metric": "us-gaap:Revenues",
  "kind": "absolute",
  "value": 78.4,
  "unit": "USD",
  "frame": null,
  "raw_sentence": "Co. reported 1Q17 revenues of $78.4b",
  "confidence": "medium"
},
```

What's working well

- Extracts explicit numeric claims reliably.
- Handles unit normalization (million vs billion).
- Distinguishes growth vs absolute value.
- Preserves context for explainability

Limitations

- Vague claims ("strong growth") are not verifiable.
- Non-GAAP phrases require deeper modeling.
- Some claims lack explicit timeframe.

Track B: Ingesting the Regulatory Source of Truth

SOURCE
SEC CompanyFacts API

FORMAT
Machine-Readable XBRL Data

STANDARD
GAAP Concepts

Rigid Backbone of Facts

The system fetches:

- CompanyFacts JSON
- Relevant US-GAAP metrics
- Period start/end dates
- Units and filing context

These records are cached locally

Filtering and Normalizing Noisy SEC Data

01

Form Filtering

Restricting ingestion to relevant 10-K and 10-Q forms

02

Period Filtering

Isolating specific fiscal years and quarters

03

Unit Normalization

Standardizing scale (millions vs. billions), USD, % values, share counts and format

04

Frame Alignment

Syncing transcript quarters with SEC period end dates

Output is a clean, queryable financial fact layer – Used by Verification Engine

The Verification Engine: Where Logic Meets Data

Step 1: Metric Canonicalization

Transcript phrases are mapped to canonical SEC tags

- Net income → NetIncomeLoss
- Cash on hand → CashAndCashEquivalentsAtCarryingValue

Step 2: Select the Best SEC Data Point

- Searches all candidate tags
- Filters by correct unit type and matches exact period end when possible
- Prefers consolidated-level facts over segment-level or mismatched dimensions

This reduces false inaccuracies caused by wrong tag selection

Step 3: Verifying Absolute Values and Growth

A) Absolute Value Claims

Compare Claim Value vs. SEC Value

Logic: Apply relative tolerance checks to account for rounding

B) Growth Claims (YoY/QoQ)

1. Retrieve Current Period Value
2. Retrieve Prior Period Value
3. Compute Delta: (Current – Prior) / Prior
4. Compare Computed Growth VS Claimed %

C) Derived Metrics

Computing composite metrics to reduce 'Unverifiable' verdicts

Cash + Marketable Securities

The Output: Verdict, Delta, and Explanation

1. Verified
2. Inaccurate
3. Unverifiable

```
==================================
  VERIFICATION RESULTS: AAPL
==================================
  Total claims:  181
  VERIFIED:      38
  INACCURATE:    110
  UNVERIFIABLE:  33
==================================
```

VERDICT: VERIFIED

```
{
    "quarter": "Q1",
    "verdict": "VERIFIED",
    "sec_metric": "us-gaap:Revenues",
    "kind": "absolute",
    "claim_value": 78.4,
    "claim_unit": "USD",
    "sec_value": 78.351,
    "sec_unit": "USD",
    "delta": 0.049000000000006594,
    "delta_pct": 0.06253908692933924,
    "explanation": "SEC value: 78.35 USD.",
    "raw_sentence": "$78.4b"
  },
```

System Evaluation: Validated Success

End-to-End Automation → Reliable flow from Transcript to Verdict

Unit Handling → Million/Billion mismatches resolved correctly

Transparent Explanation → Every verdict includes reasoning and source data

Improved Tag Matching → Advanced selection logic reduces false negatives

Growth Calculation working → Pulls current and prior SEC values, calculates YoY or QoQ growth, verifies it against the claimed percentage, and allows rounding tolerance

System Evaluation: Current Limitations

1 Growth Fragility

- If prior-period SEC value is unavailable, growth cannot be computed
- Missing frames or mismatched fiscal periods cause UNVERIFIABLE/INACCURATE verdicts

2 Metric Mapping Gaps

- Some transcript phrases do not map cleanly to GAAP tags
- Ambiguous mapping leads to UNVERIFIABLE/INACCURATE verdicts

3 Non-GAAP

- “Adjusted EPS” or “Revenue excluding FX” require reconciliation tables
- SEC CompanyFacts only contains GAAP values
- System does not model non-GAAP adjustments

4 Fiscal Quarter Alignment

- Companies have different fiscal year ends
- Was working on fix but not yet solved completely

5 Vague Phrasing

Subjective claims like “Strong growth” remain outside scope

Hybrid Approach for Claim Extraction

Earnings Transcript

- Unstructured
- Conversational
- Inconsistent

LLM = Language Understanding

- Detects financial claims
- Understands varied phrasing
- Classifies: Absolute | Growth | Margin
- Extracts timeframe

Rules Based Normalization

- Parse numbers deterministically
- Normalize units
- Validate % and timeframe
- Output clean structured JSON

```
[2017-Aug-01-AAPL.txt] Extracting (mapped to Q3)...
      → 67 claims extracted

[2017-Jan-31-AAPL.txt] Extracting (mapped to Q1)...
      → 47 claims extracted

[2017-May-02-AAPL.txt] Extracting (mapped to Q2)...
      → 38 claims extracted

[2017-Nov-02-AAPL.txt] Extracting (mapped to Q4)...
      → 29 claims extracted
```

LLM interprets meaning

Rules validate numbers

Result: Flexible understanding + deterministic accuracy

Final Conclusions

1. Built an End-to-End Financial Claim Verification System
2. Hybrid Architecture Enables Both Flexibility and Accuracy
3. Explainable, Transparent Outputs
    - Shows SEC tag used
    - Displays official value
    - Calculates delta
    - Provides clear reasoning for each verdict
4. Handles Multiple Claim Types
    - Absolute values, Growth (YoY / QoQ), Margins, Derived financial metrics
5. Modular and Extensible Design
    - Independent transcript and SEC pipelines
    - Verification logic can scale
    - Future enhancements possible

Architecture is modular, extensible, and transparent

Future Scope

Currently, verification is deterministic and rule-based. Future improvements could incorporate LLM support in specific areas.

Context-Aware Claim Classification

LLMs could help:

- Distinguish GAAP vs Non-GAAP claims
- Detect when executives are referencing segment-level vs consolidated numbers
- Identify guidance vs reported results

This would reduce false UNVERIFIABLE classifications.

Non-GAAP Reconciliation Modeling

LLMs could:

- Parse reconciliation tables in filings
- Identify adjustment components
- Help reconstruct adjusted metrics

This would allow verification of “Adjusted EPS” or “Revenue excluding FX”

Improved Metric Mapping

LLMs could assist in:

- Mapping ambiguous transcript phrases to correct GAAP tags
- Understanding nuanced phrasing (e.g., “core operating earnings”)
- Suggesting likely tag candidates when rule-based mapping fails

This strengthens the transcript → GAAP mapping layer

Confidence Scoring

LLMs could assist in:

- Assessing ambiguity in metric mapping
- Evaluating contextual clarity
- Supporting probabilistic confidence scoring per verdict

Even with LLM enhancements, numeric truth comparison will remain deterministic and rule-based

THANK YOU
